

Olist E-Commerce Sales & Delivery Analytics

From raw e-commerce data to a decision-ready Power BI dashboard - total revenue, delivery performance and geography of sales, 2017-2018.

- **Data source**

Kaggle Brazilian E-Commerce Public Dataset by Olist

What the dataset covers, and what we set out to build

Olist is a Brazilian marketplace connecting small merchants to major retail channels. Its public dataset traces **real, anonymized orders** from purchase to delivery to customer review.

The goal: turn 9 raw relational tables into a single analytical model that answers concrete revenue, logistics, and geographic questions. Then surface them in an interactive Power BI dashboard.

100 K+

Orders, 2017-2018

● Pipeline & SQL Repository

<https://github.com/serhiy-dranko/olist-e-commerce-dataset>

● Delivery tool

Power BI Desktop: data model + interactive report.

Three business questions the dashboard answers

1

Revenue trend by category

Is revenue growing or shrinking, and which categories drive it?

2

Delivery time vs. review score

Do late/slow deliveries correlate with lower review scores?

3

State-level performance

Where is the business strong or weak geographically?

Data schema: tables & columns behind each question

- **Revenue by category**

TABLES

orders · order_items · products ·
product_category_name_translation

COLUMNS

order_purchase_timestamp, price,
product_id → product_category_name
→ product_category_name_english

- **Delivery time vs. review**

TABLES

orders · order_reviews

COLUMNS

order_purchase_timestamp,
order_delivered_customer_date,
order_estimated_delivery_date
→ review_score

- **State-level performance**

TABLES

orders · customers · order_reviews

COLUMNS

customer_id → customer_state,
order_id → review_score

From 9 CSV files to a queryable semantic model

1 Extract

9 raw Kaggle CSVs

(orders, items, customers, products, payments, reviews, sellers, geolocation, category translation) loaded as source tables.

2 Transform

Power Query / SQL:

Type casting, de-duplication, key cleanup and calculated fields: delivery_time_days, state_grouped, pCat_grouped.

3 Model

Tables joined into a main- table:

A wide detail table (main_sales_orders_detail) plus lookup dimensions (states, category translation).

4 Serve

DAX measures

Total Revenue, Order Count, Avg Review Score.
Built in the interactive Power BI report and slicers.

What the data shows

• Revenue grew, then plateaued

Monthly revenue climbed through 2017, spiked to R\$178K on the Nov 24, 2017 Black Friday, then stabilized around R\$1M/month through mid-2018.

• Slower delivery → lower reviews

Avg. review score falls from 4.33 (0–7 day delivery) to 1.80 for undelivered orders. It's a clear, near-linear relationship.

• Sao Paulo dominates, but the tail matters

Sao Paulo alone drives 37% of revenue. The next 9 an Othe combined states combined still contribute the majority of the remainder.

Thank you for your attention!
I will be happy to answer your questions.
